# Development progress 1.2

## About the data

The indicators in this table are intended to measure progress toward the international development goals. The net enrollment ratio, infant and under-five mortality rates, maternal mortality ratio, and access to safe water are included in the set of 28 social and environmental indicators selected for monitoring development progress by the Organisation for Economic Co-operation and Development, the World Bank, and the United Nations in consultation with countries that provide and those that receive development assistance.

The growth of private consumption per capita is included here as an indicator of the effect of economic development on income poverty. Positive growth rates are generally associated with a reduction in poverty, but where the distribution of income or consumption is highly unequal, the poor may not share equally in the improvement. The relationship between the rate of poverty reduction and the distribution of income or consumption, as measured by an index such as the Gini index, is complicated. But Ravallion and Chen (1997) have found that the rate of poverty reduction is directly proportional to the distribution-corrected rate of growth of private consumption per capita. The distribution-corrected rate of growth is calculated as  $(1 - G)r$ , where  $G$  is the Gini index (0 = perfect equality, 1 = perfect inequality) and  $r$  is the rate of growth in mean private consumption. The distribution-corrected growth rate may be thought of as the rate of growth in consumption that would produce the same rate of poverty reduction as the observed growth in consumption, if consumption were evenly distributed. It is not necessarily the rate of growth experienced by the poor or any other group in the economy.

In empirical tests covering 23 developing countries, Ravallion and Chen estimated that factor of proportionality to be 4.4, implying a growth elasticity of poverty reduction of between 3.3 for a low Gini index of 0.25 and 1.8 for a high Gini index of 0.60. This implies that a country such as China—with average annual growth in private consumption per capita of 7.2 percent and a Gini index of 0.4—could reduce its poverty rate by 1.8 percentage points a year on average. China's actual experience may have been different because the distribution of income or consumption may change over time.

Estimates of the share of people living in poverty appear in table 2.7. Discussions of the other indicators can be found in *About the data* for tables 2.10 (net enrollment ratio), 2.16 (maternal mortality ratio), 2.18 (infant and under-five mortality rates), and 2.15 (access to safe water).

## Definitions

- **Growth of private consumption per capita** is the average annual rate of change in private consumption divided by the midyear population. For the definition of private consumption see *Definitions* for table 4.10.
- **Distribution-corrected growth of private consumption per capita** is 1 minus the Gini index multiplied by the annual rate of growth in private consumption per capita.
- **Net primary enrollment ratio** is the ratio of the number of children of official school age (as defined by the education system) enrolled in school to the number of children of official school age in the population.
- **Infant mortality rate** is the number of deaths of infants under one year of age during the indicated year per 1,000 live births in the same year.
- **Under-five mortality rate** is the probability of a child born in the indicated year dying before reaching the age of five, if subject to current age-specific mortality rates. The probability is expressed as a rate per 1,000.
- **Maternal mortality ratio** is the number of women who die during pregnancy and childbirth, per 100,000 live births.
- **Access to safe water** is the percentage of the population with reasonable access to an adequate amount of safe water (including treated surface water and untreated but uncontaminated water, such as from springs, sanitary wells, and protected boreholes). In urban areas the source may be a public fountain or standpipe located not more than 200 meters away. In rural areas the definition implies that members of the household do not have to spend a disproportionate part of the day fetching water. An adequate amount of safe water is that needed to satisfy metabolic, hygienic, and domestic requirements—usually about 20 liters a person a day. The definition of safe water has changed over time.

## Data sources

The indicators here and throughout the rest of the book have been compiled by World Bank staff from primary and secondary sources. More information about the indicators and their sources can be found in the *About the data*, *Definitions*, and *Data sources* entries that accompany each table in subsequent sections.
